

# Basic Arithmetic

We'll do it tomorrow

– TODO

We'll start by giving a formal account of the simplest practical language – that of *first-order* arithmetic expressions, like  $x + y$  and  $a + (5 \cdot b) + \sin(3)$ .

Rather than complicate our language by introducing binary operators (like  $x + y$ ), unary operators (like  $-x$ ), and  $n$ -ary function applications (like  $f(x, y, z)$ ), we can instead normalize everything to *S-expressions* – or *sexprs* – of the form  $(f e_1 \dots e_n)$ . We can then uniformly write:

- binary operations like  $x + y$  as binary sexprs  $(+ x y)$ ,
- unary operations  $-x$  as unary sexprs  $(- x)$ ,
- function applications  $f(x, y, z)$  as  $n$ -ary sexprs  $(f x y z)$ .

In particular, the *operator*  $f$  always comes first, and there is no order-of-operations – all bracketing is explicit. Restricting ourselves to *first-order* sexprs means that we always require operators  $f$  to be atomic symbols drawn from a fixed set  $O$  – in particular, we don't support *partial application*, like  $((\text{add } 2) 3)$ , since that would require  $f = (\text{add } 2)$  to be a compound expression.

Formally, we define our untyped *syntax* as follows:

**Definition 0.1** (First-order S-expressions): Fixing

- a set of *variables*  $x \in N$
- a set of *operations*  $f \in O$
- a set of *constants*  $c \in V$

we define the set of *first-order S-expressions*  $e \in \text{STm}_N(O, V)$  to be given by the grammar

$$e ::= x \mid c \mid (f e^*)$$

We can define a typing relation over this syntax, parametrized by a set of types  $A \in \mathcal{T}$ , in the usual manner. We begin by fixing some conventions:

**Definition 0.2** (Typing Context): Given a set of variables  $N$  and a set of types  $\mathcal{T}$ , we define the set of *contexts*  $\Gamma : \text{Ctx}_N(\mathcal{T})$  to be the set of lists of bindings  $x : A$ , given by the grammar

$$\Gamma ::= \cdot \mid \Gamma, x : A \text{ where } x \notin \text{def}(\Gamma)$$

Here,  $\text{def}(\Gamma)$  denotes the set of *defined variables* in  $\Gamma$ , defined as

$$\text{def}(\cdot) = \emptyset \qquad \text{def}(\Gamma, x : A) = \text{def}(\Gamma) \cup \{x\}$$

Given a context  $\Gamma$ , we can hence define a partial function from variables  $N$  to types  $\mathcal{T}$  as follows:

$$(\text{pty}(\Gamma), x : A)(x) := A \qquad \text{pty}(\Gamma, y : A)(x) := \text{pty}(\Gamma)(x) \text{ where } x \in \text{def}(\Gamma)$$

It follows that we can view a context  $\Gamma$  as isomorphic to:

- a *finitely supported partial function*  $\text{pty}(\Gamma) : N \rightarrow \mathcal{T}$  – where the support of  $\Gamma$  is the set of defined variables  $\text{def}(\Gamma)$
- a *total order* on the set of defined variables  $\text{def}(\Gamma)$  – given by the order in which they appear in the context

In general, we'll define  $\Gamma(x) := \text{pty}(\Gamma)(x)$ .

**Definition 0.3** (Typed Constants): We define a set of *typed constants*  $c \in V$  to be a set  $V$  equipped with a *typing relation*  $V \rightarrow \mathcal{T}$  – written  $c : A$  to mean “ $c$  has type  $A$ ”.

Note that constants are typed with a *relation* – that is, the same constant  $c$  can be assigned multiple types  $A, B, C$ .

**Definition 0.4** (Typed Operations): We define a set of *typed operations*  $f \in O$  to be a set  $O$  equipped with a *typing relation*  $O \times \mathcal{T}^* \rightarrow \mathcal{T}$  – written  $f : [A_1, \dots, A_m] \rightarrow B$  to mean “ $f$  takes inputs  $[A_1, \dots, A_m]$  to output  $B$ ”.

We've now got what we need to define a well-typed first-order S-expressions:

**Definition 0.5** (Typed First-order S-expressions): Fixing

- a set of *variables*  $x \in N$
- a set of *typed operations*  $f \in O$  equipped with a *typing relation*  $O \times \mathcal{T}^* \rightarrow \mathcal{T}$  – where “ $f$  takes inputs  $[A_1, \dots, A_m]$  to output  $B$ ” is written  $f : [A_1, \dots, A_m] \rightarrow B$
- a set of *typed constants*  $c \in V$  equipped with a *typing relation*  $V \rightarrow \mathcal{T}$  – where “ $c$  has type  $A$ ” is written  $c : A$

we define a typing relation on first-order S-expressions  $e$  via the following rules:

- **TODO 1: Var**
- **TODO 2: Const**
- **TODO 3: Op**

**TODO 4: Subtyping, weakening and substitution**

**TODO 5: Define the denotational semantics**

- **Pure**
- **Monadic**
- **Categorical**
